$$

All genealogies were simulated with the same population size $N_{e}=10,000$

## Variability of the coalescent process

## Population Parameter Inference

## Population Parameter Inference

## Population model

The relationship among individuals can be expressed, looking backward in time, by a waiting process where random lineages
coalesce
migrate between populations
split off an ancestral population

## Population genetics

Each of these processes can be expressed as a waiting time process with rate $\lambda$ for $N$ populations and $k_{j}$ lineages in population $j$ :

*using a Normal distribution to model the splitting time between two populations.

$$
\begin{aligned}
\lambda_{\mathrm{two} \text { lineages coalesce }} & =\sum_{j=1}^{N} \frac{k_{j}\left(k_{j}-1\right)}{4 N} \\
\lambda_{\text {lineages migrate }} & =\sum_{j=1}^{N} \sum_{i=1, i \neq j}^{N} k_{j} m_{i j} \\
\lambda_{\text {lineages split off }}{ }^{*} & =\frac{k \sqrt{\frac{2}{\pi}} e^{\frac{(t-\mu)^{2}}{2 \sigma^{2}}}}{\sigma\left(1-\operatorname{erf}\left(\frac{t-\mu}{\sqrt{2} \sigma}\right)\right)}
\end{aligned}
$$

## Combining the parts

$$
P\left(\Theta \mid \mathbf{D}_{1}, \mathbf{D}_{2}, \ldots, \mu\right)=\frac{P(\Theta) P\left(\mathbf{D}_{1}, \mathbf{D}_{2}, \ldots \mid \Theta\right)}{P\left(\mathbf{D}_{1}, \mathbf{D}_{2}, \ldots\right)}=\frac{P(\Theta) \int_{G} P(G \mid \Theta) \prod_{i}^{n_{\text {Loci }}} P\left(\mathbf{D}_{\mathbf{i}} \mid G, \mu\right) d G}{\int_{\Theta} P(\Theta) \int_{G} P(G \mid \Theta) \prod_{i}^{n_{\text {Loci }}} P\left(\mathbf{D}_{\mathbf{i}} \mid G, \mu\right) d G d \Theta}
$$

$$
P(G \mid \Theta)=\prod_{i=1}^{K} \lambda_{x} \exp \left(-t_{i}\left[\lambda_{\text {coalescence }}+\lambda_{\text {migration }}+\lambda_{\text {spliting }}\right]\right)
$$

$\Theta \quad$ vector of parameters for population size, migration and splitting parameters.
$\mathrm{D}_{1}, \mathrm{D}_{2}, \ldots$ independent genetic sequence data, mutation model, nuisance genealogies that we integrate out (we are interested in the parameters not the trees). the particular event on the genealogy
$4 K / 77$ ©2023 Peeter Beent

## Finally....

$$
p(D \mid \Theta)=\int_{G} p(G \mid \Theta) p(D \mid G) d G
$$

The number of possible genealogies is very large and for realistic data sets, programs need to :use Markov chain Monte Carlo methods:

## So many models - so little time

## Gene flow

## Divergence and Gene flow

Neanderthal

Present
'Modern' human

## Even more different structural models

## Model comparison

With a criterium such as likelihood we can compare nested models. Commonly we use a likelihood ratio test (LRT) or Akaike's information criterion (AIC) to establish whether phylogenetic trees are statistically different or mutation models have an effect on the outcome, etc.

Kass and Raftery (1995) popularized the Bayes Factor as a Bayesian alternative to the LRT.

## Bayesian inference

60/77 ©2023 Peter Beerli

## Bayes factor

Theoretically, we can calculate the posterior probability density of the model

$$
\mathrm{p}\left(\mathrm{M}_{1} \mid \mathrm{X}\right)=\frac{\mathrm{p}\left(\mathrm{M}_{1}\right) \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}(\mathrm{X})}
$$

## Bayes factor

Theoretically, we can calculate the posterior probability density of the model 1 and model 2

$$
\begin{aligned}
& \mathrm{p}\left(\mathrm{M}_{1} \mid \mathrm{X}\right)=\frac{\mathrm{p}\left(\mathrm{M}_{1}\right) \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}(\mathrm{X})} \\
& \mathrm{p}\left(\mathrm{M}_{2} \mid \mathrm{X}\right)=\frac{\mathrm{p}\left(\mathrm{M}_{2}\right) \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}(\mathrm{X})}
\end{aligned}
$$

## Bayes factor

Theoretically, we can calculate the posterior probability density of the model 1 and model 2

$$
\frac{\mathrm{p}\left(\mathrm{M}_{1} \mid \mathrm{X}\right)}{\mathrm{p}\left(\mathrm{M}_{2} \mid \mathrm{X}\right)}=\frac{\frac{\mathrm{p}\left(\mathrm{M}_{1}\right) \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}(\mathrm{X})}}{\frac{\mathrm{p}\left(\mathrm{M}_{2}\right) \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}(\mathrm{X})}}
$$

## Bayes factor

We could look at the posterior odds ratio or equivalently the Bayes factors.

$$
\frac{\mathrm{p}\left(\mathrm{M}_{1} \mid \mathrm{X}\right)}{\mathrm{p}\left(\mathrm{M}_{2} \mid \mathrm{X}\right)}=\frac{\mathrm{p}\left(\mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{M}_{2}\right)} \times \frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)}
$$

$$
\mathrm{BF}=\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)} \quad \mathrm{LBF}=2 \ln \mathrm{BF}=2 \ln \left(\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)}\right)
$$

## Bayes factor

$$
\mathrm{BF}=\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)} \quad \mathrm{LBF}=2 \ln \mathrm{BF}=2 \ln \left(\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)}\right)
$$

The magnitude of BF gives us evidence against or for hypothesis $M_{2}$

$$
\mathrm{LBF}=2 \ln \mathrm{BF}=z \quad \begin{cases}0<|z|<2 & \text { No real difference } \\ 2<|z|<6 & \text { Positive } \\ 6<|z|<10 & \text { Strong } \\ |z|>10 & \text { Very strong }\end{cases}
$$

## Bayes factor example

$$
\mathrm{LBF}=2 \ln \mathrm{BF}=2 \ln \left(\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{1}\right)}{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{2}\right)}\right)=2(-9638.69)-(-9641.01)=4.64
$$

The magnitude of BF gives us evidence against or for hypothesis $M_{2}$

$$
\mathrm{LBF}=2 \ln \mathrm{BF}=z \quad \begin{cases}0<|z|<2 & \text { No real difference } \\ 2<|z|<6 & \text { Positive } \\ 6<|z|<10 & \text { Strong } \\ |z|>10 & \text { Very strong }\end{cases}
$$

## Posterior model probability

Instead of calculating the Bayes factor we could use the probability of all tested models $M_{i}$ and use them as weights (cf. Burnham and Anderson,1998)

$$
\begin{aligned}
p_{i}^{*} & =\frac{\mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{\mathrm{i}}\right)}{\sum_{j} \mathrm{p}\left(\mathrm{X} \mid \mathrm{M}_{\mathrm{j}}\right)}, \quad \sum_{i} p_{i}^{*}=1, \quad \ell_{1}=-9638.61, \quad \ell_{2}=-9641.01 \\
p_{1}^{*} & =\frac{\exp \left(\ell_{1}\right)}{\exp \left(\ell_{1}\right)+\exp \left(\ell_{2}\right)}=0.911 \\
p_{2}^{*} & =\frac{\exp \left(\ell_{2}\right)}{\exp \left(\ell_{1}\right)+\exp \left(\ell_{2}\right)}=0.089
\end{aligned}
$$

## Marginal likelihood

Typically, it is rather difficult to calculate the marginal likelihoods with good accuracy, because most often we only approximate the posterior distribution using Markov chain Monte Carlo (MCMC).
In MCMC we need to know only differences and therefore we typically do not need to calculate the denominator to calculate the Posterior distribution $\mathrm{p}(\Theta \mid \mathrm{X})$ :

$$
p(\Theta \mid X, M)=\frac{p(\Theta) p(X \mid \Theta)}{p(X \mid M)}=\frac{p(\Theta) p(X \mid \Theta)}{\int_{\Theta} p(\Theta) p(X \mid \Theta) d \Theta}
$$

where $p(X \mid M)$ is the marginal likelihood, which we need for our model selection!

## Estimation of the marginal likelihood

$\rightarrow$
Harmonic mean estimator [Kass and Raftery 1995]: methods is easy and used in many programs, results are biased and overestimate the marginal likelihood, variance of estimates can be very large.

Thermodynamic integration (Path sampling) [Gelman and Meng 1997, Lartillot et al. 2006]: method is tedious to compute because several MCMC chains are needed. Results are accurate and reproducible with small variance when MCMC runs were run long enough.

Stepping stone approach (Xie et al. 2011)

## Summary

You may be surprised that your favored model does not win in a model comparison competition, but figuring out the model order leads oftentimes to new insights about the problem.

Models by themselves are not true or wrong. BUT they may not fit your data well, OR they describe your data even when you "know" that the model is insufficient.

## Thank you
